## DINA-CH full tokamak simulator

Jo Lister, Karim Besseghir

*CRPP-EPFL, Lausanne, Switzerland*

Comments from Sun Hee Kim (*ITER*) Rémy Nouailletas (*CEA*)

ÉCOLE POLYTECHNIQUE  
FÉDÉRALE DE LAUSANNE

8 November 2010

## Topics

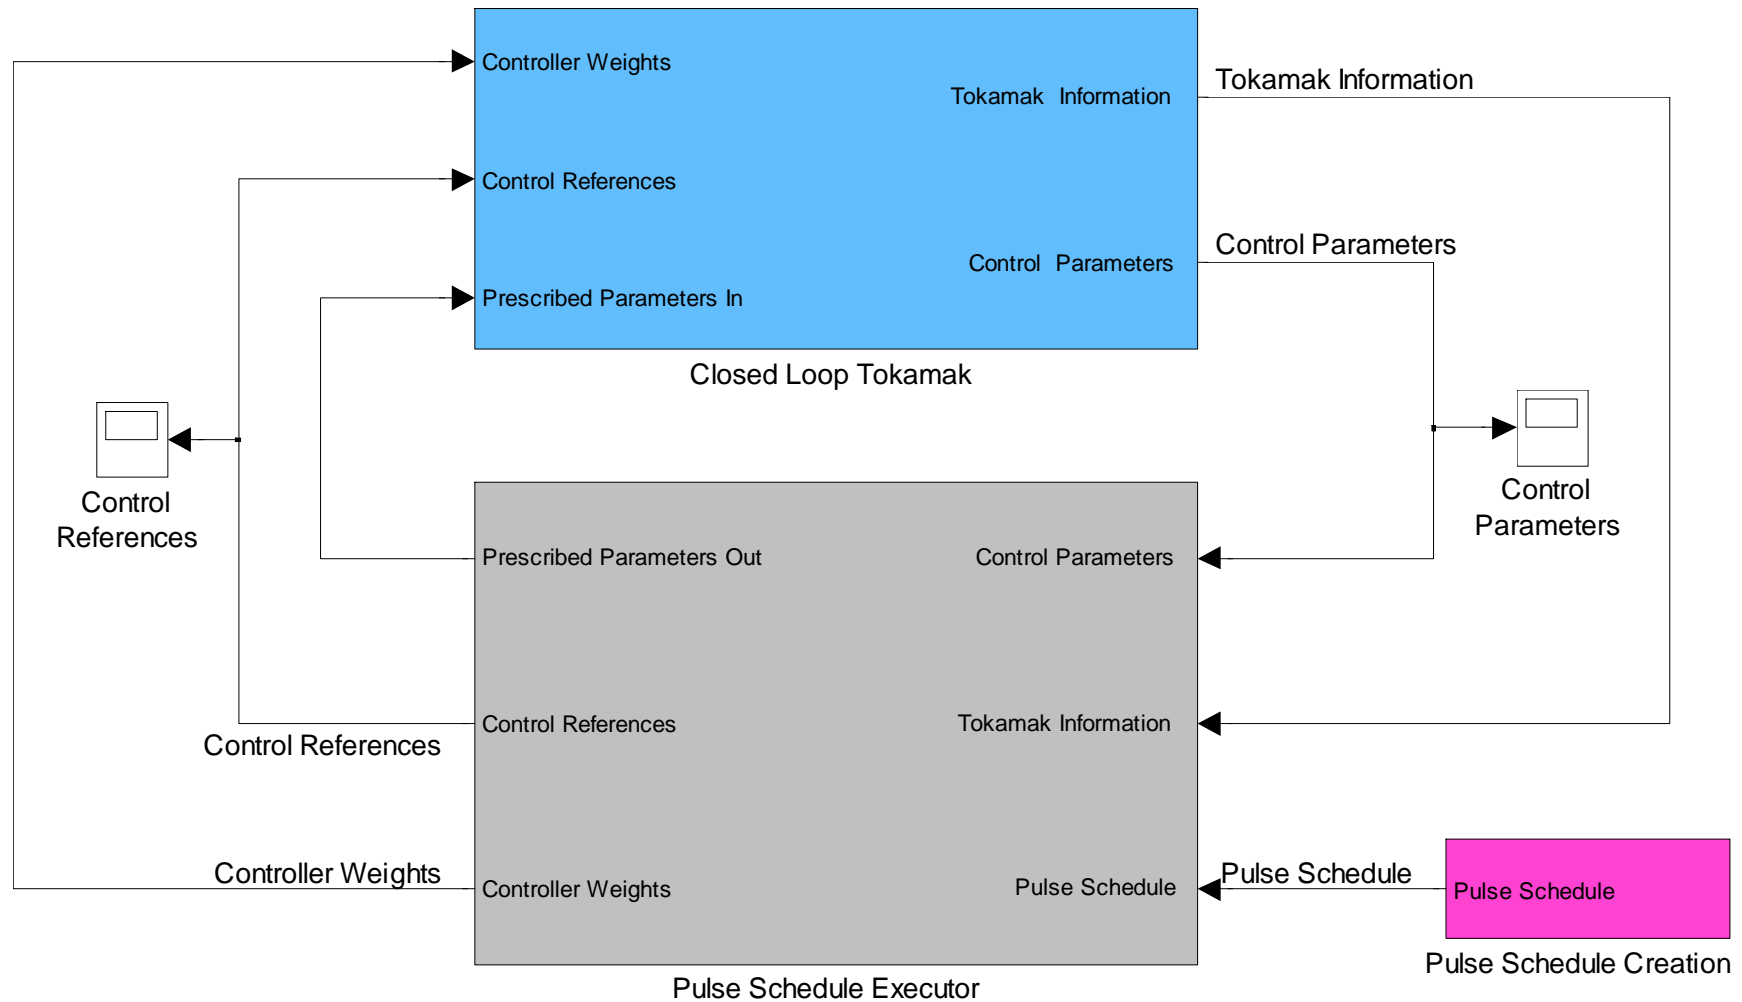

- What are we trying to do with DINA-CH ?
- Experience coupling with CRONOS ?
- Lessons learned throughout ?
  
- What are the general issues which are likely to be encountered before getting to where we are now ?
- Try to avoid some of the effort traps we encountered
- We will simply walk you through the components of our full tokamak simulator and point out some issues during the guided tour
- In fact, the overall structuring is part of the lessons (being)learned
- We can handle any detailed points another time, if useful to you

## Historical review

- DINA (1993) was, and still is, a stand-alone FORTRAN solver for heat transport and free-boundary equilibrium evolution
- It is in the class DINA-TSC-CORSICA
- It is a full tokamak simulator, consistent by design
  
- DINA was validated against TCV PF control experiments under the ITER Expert Group (1998). It was successful but very black-box – controllers, sources, transport all built-in
  
- DINA-CH (2001) is the “exploded” version of DINA under Simulink, with transport, sources, power supplies, controllers, diagnostics, all external to the solver – just as ITM is targeting
- DINA-CH is being extended to open field-lines for halo-currents

# Overview of the full tokamak simulator

## DINA-CH : Full Tokamak Simulator Top view of any full tokamak simulator

# Overview of the full tokamak simulator

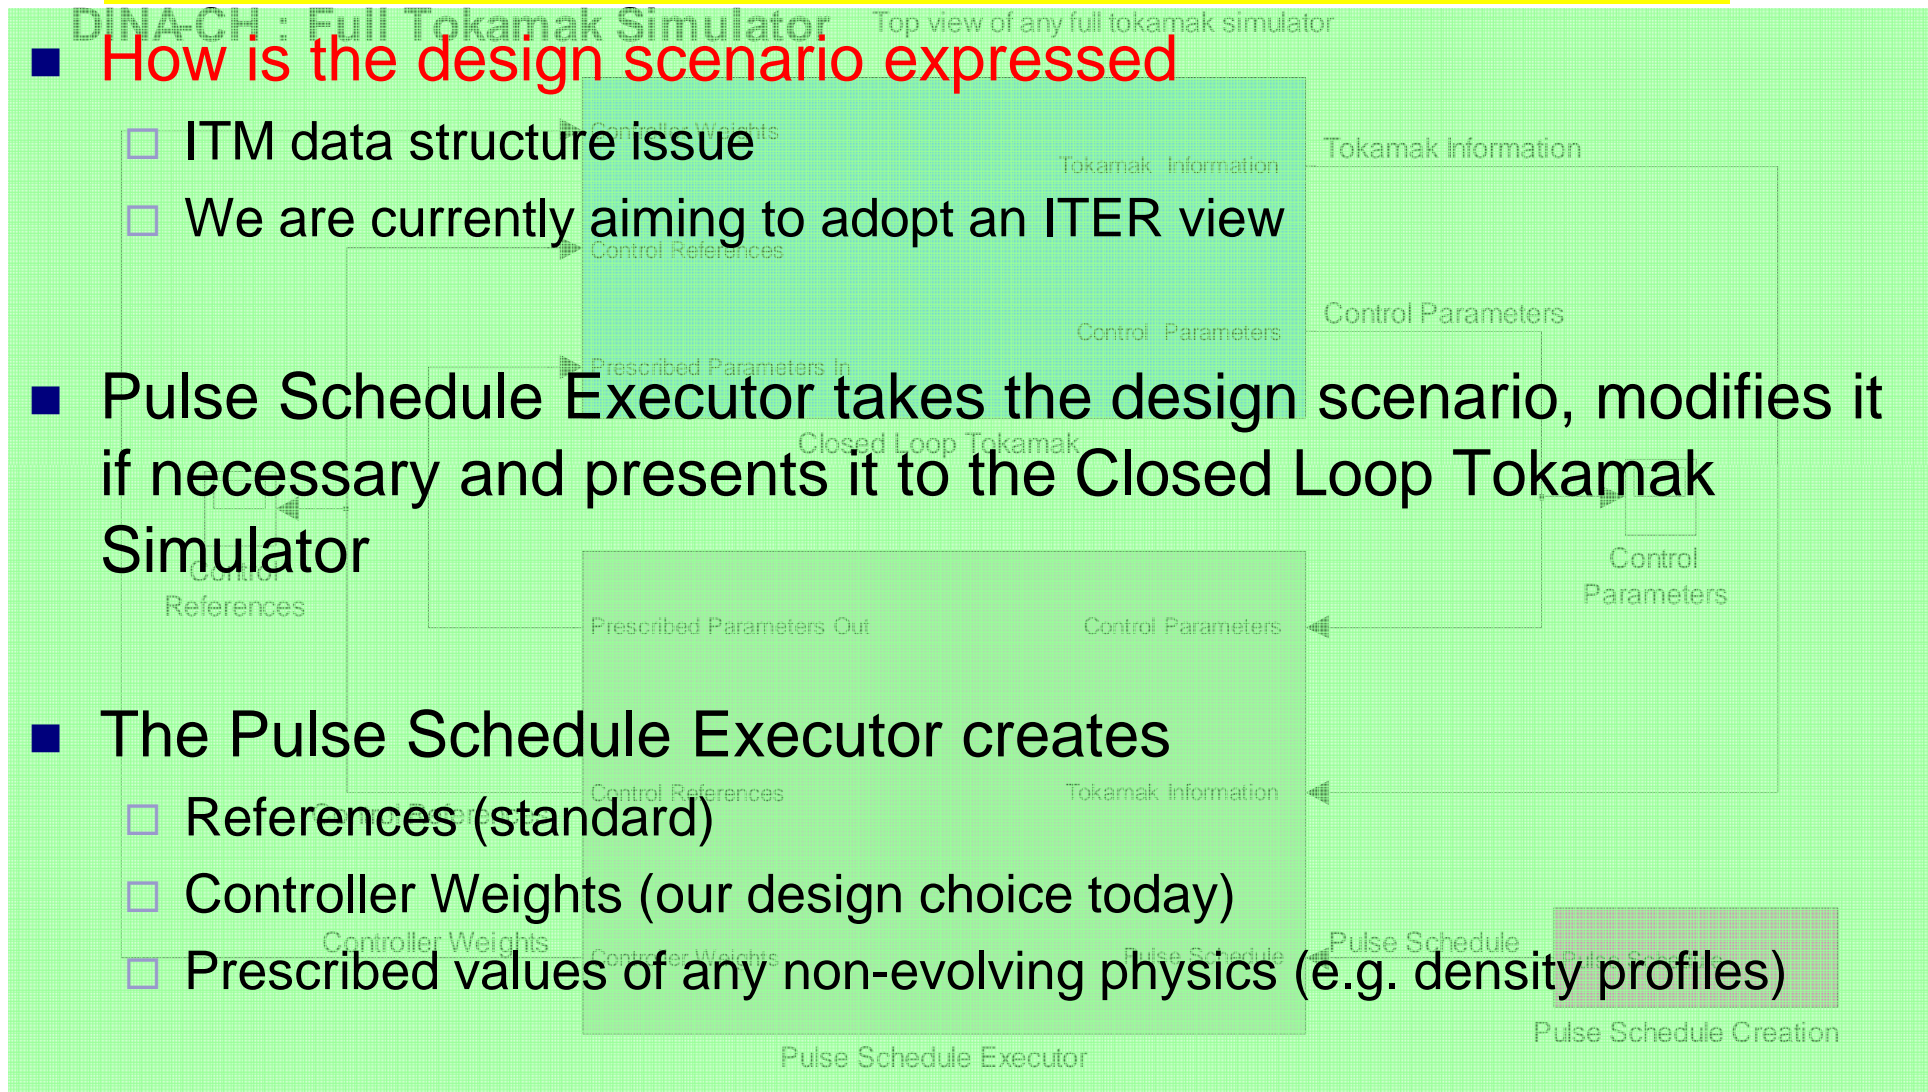

## ■ How is the design scenario expressed

- ITM data structure issue
- We are currently aiming to adopt an ITER view

## ■ Pulse Schedule Executor takes the design scenario, modifies it if necessary and presents it to the Closed Loop Tokamak Simulator

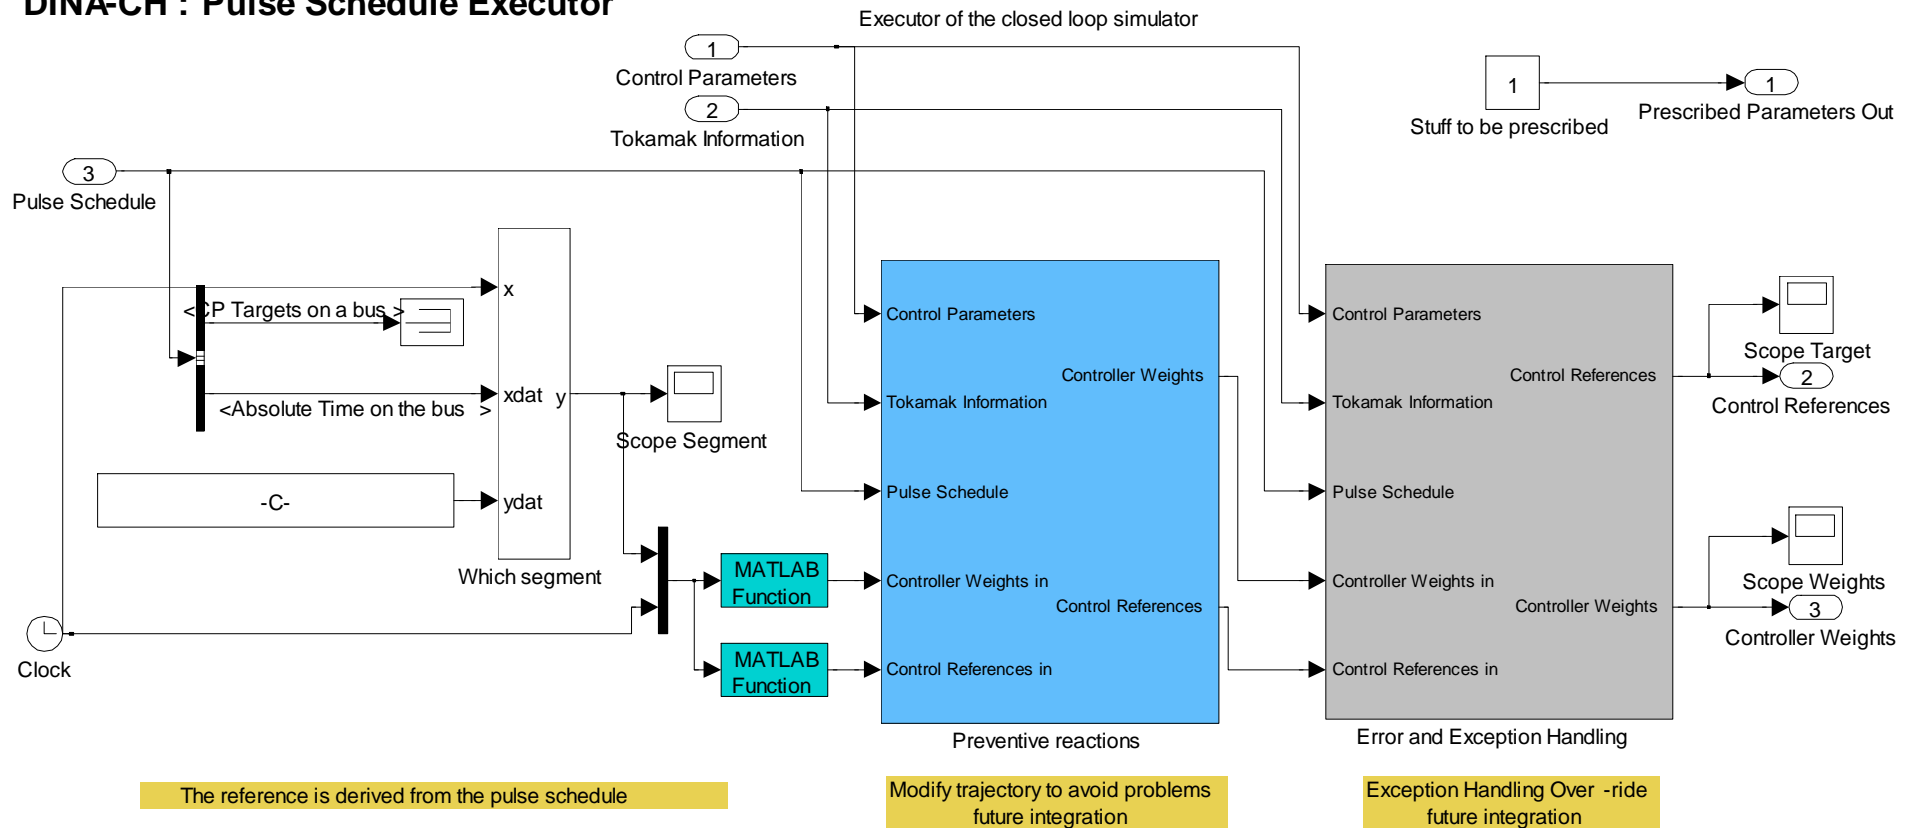

## ■ The Pulse Schedule Executor creates

- References (standard)
- Controller Weights (our design choice today)
- Prescribed values of any non-evolving physics (e.g. density profiles)

# Execute a Pulse Schedule

## DINA-CH : Pulse Schedule Executor

# Execute a Pulse Schedule

- Take design controller references and design controller weights

DINA-CH : Pulse Schedule Executor

- Over-ride them both with preventive actions

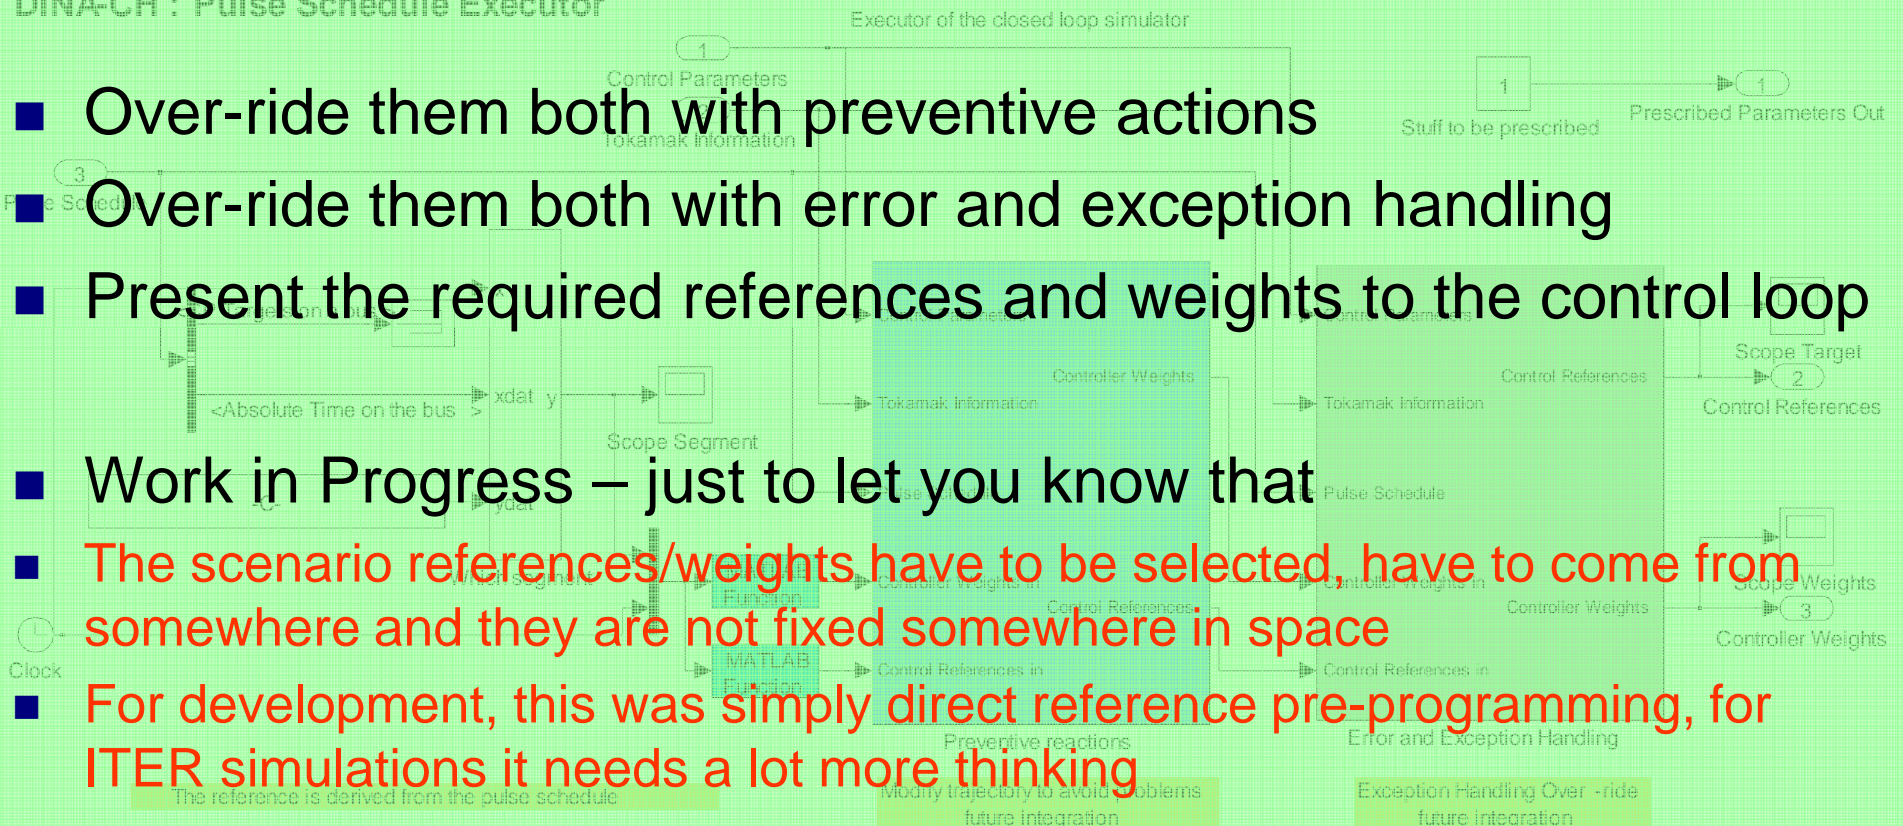

- Over-ride them both with error and exception handling

- Present the required references and weights to the control loop

- Work in Progress – just to let you know that

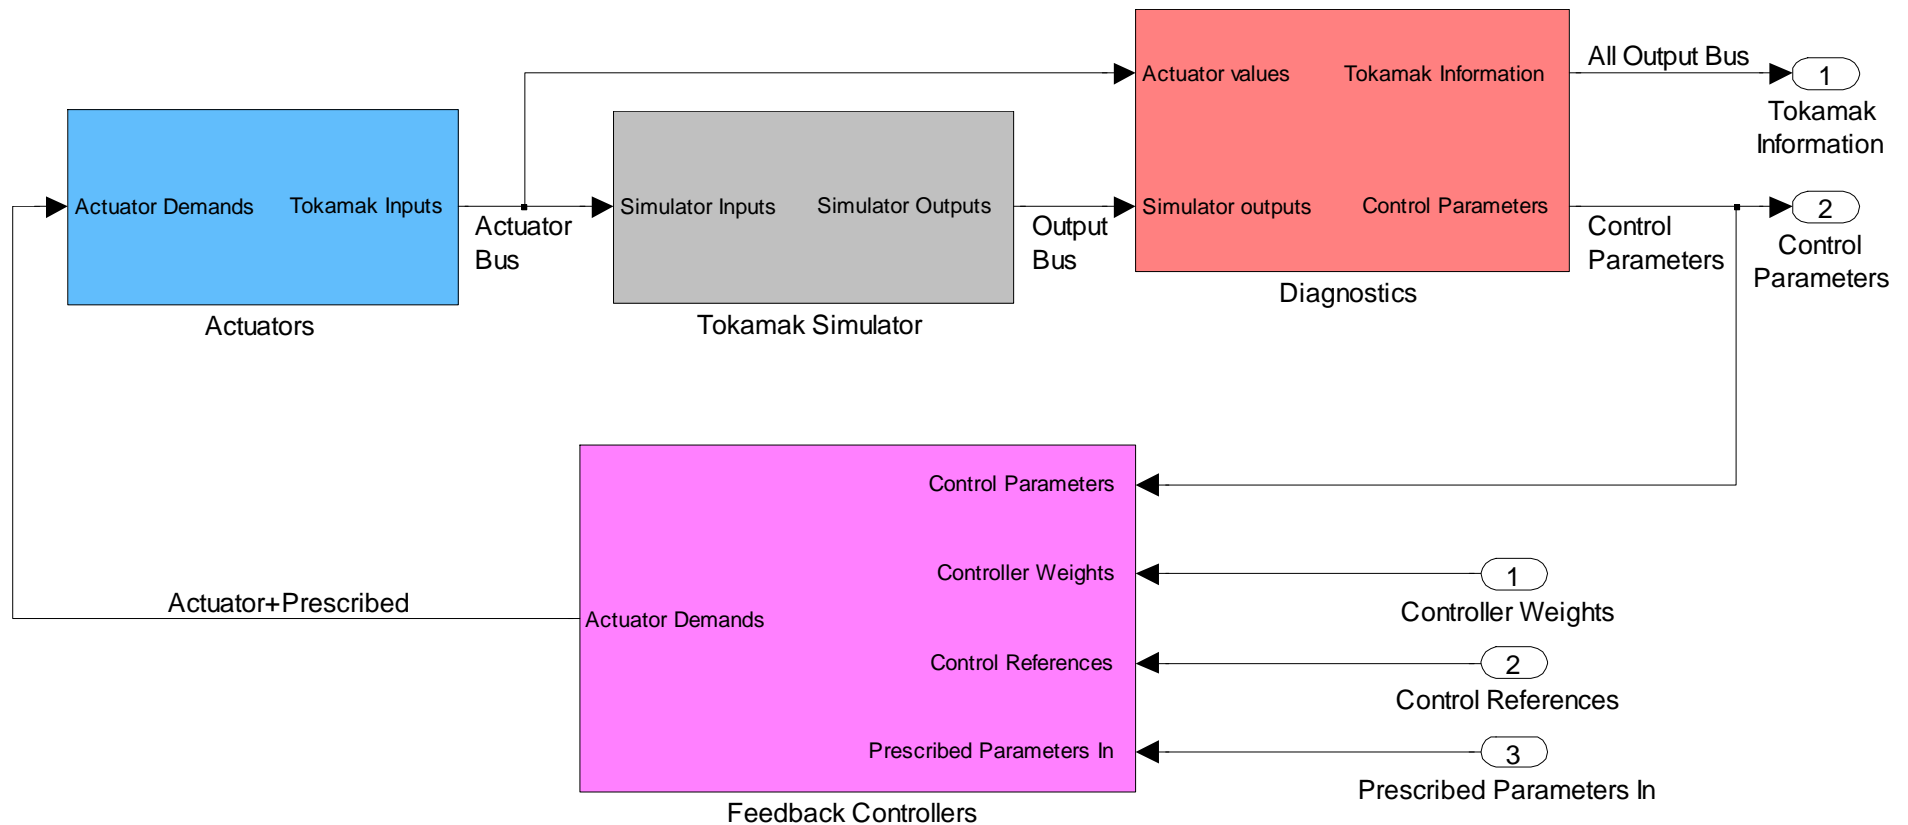

- The scenario references/weights have to be selected, have to come from somewhere and they are not fixed somewhere in space

- For development, this was simply direct reference pre-programming, for ITER simulations it needs a lot more thinking

# Simulate the Closed Loop

## DINA-CH : Closed Loop Tokamak View of the tokamak controlled in a feedback loop

# Simulate the Closed Loop

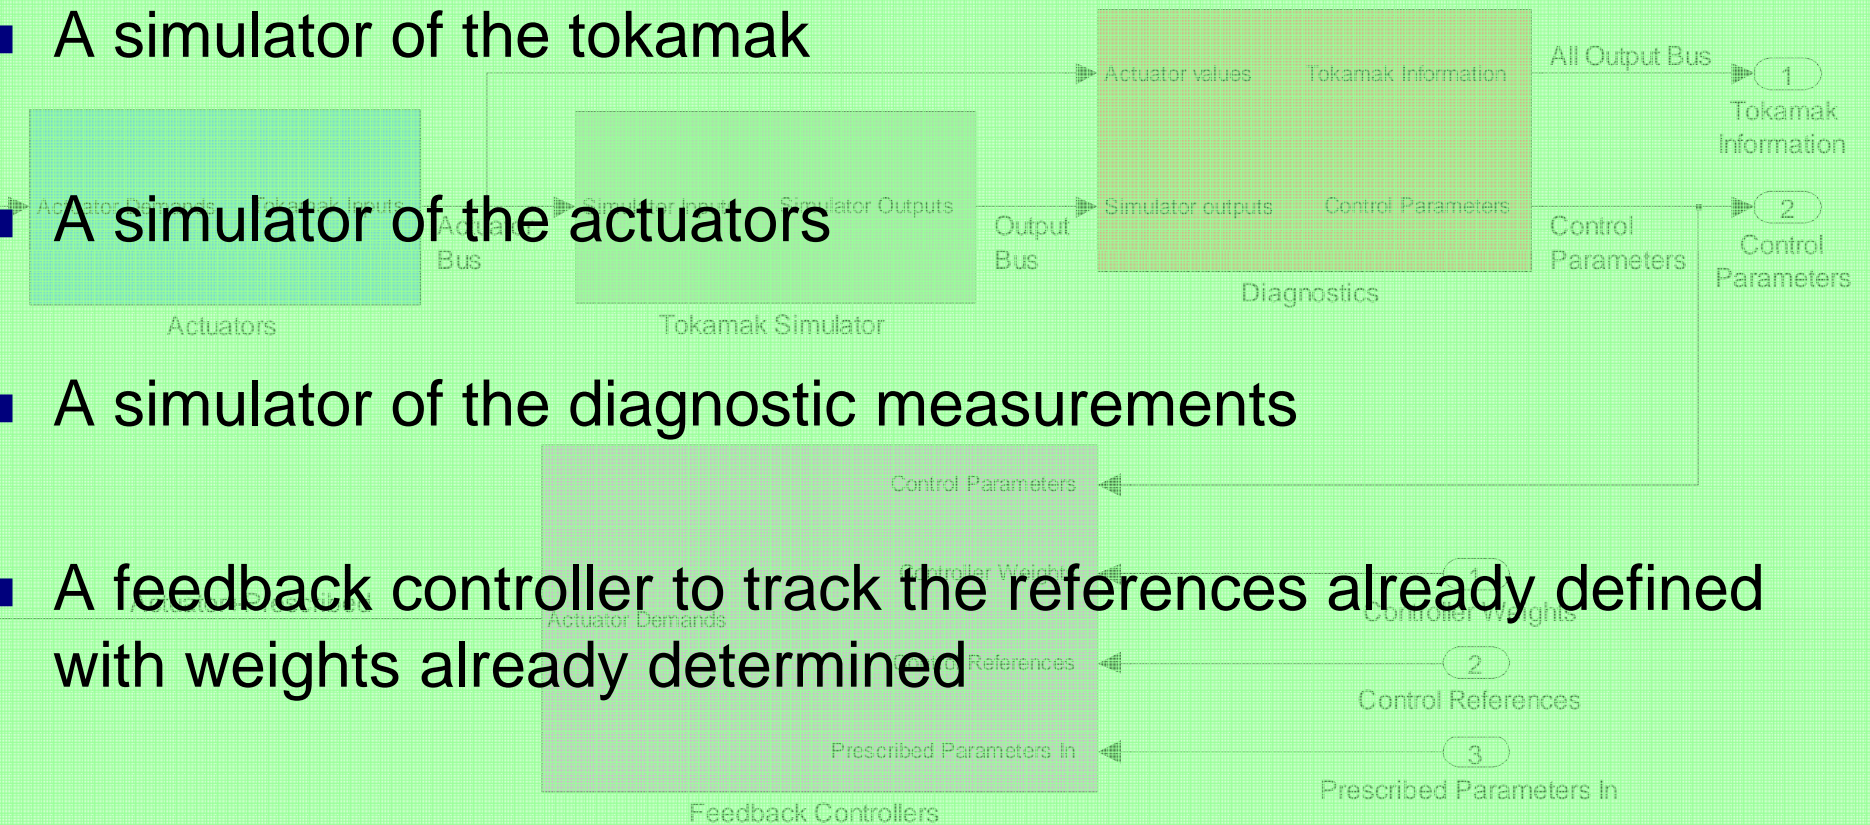

- More familiar now with 4 components:

- A simulator of the tokamak

- A simulator of the actuators

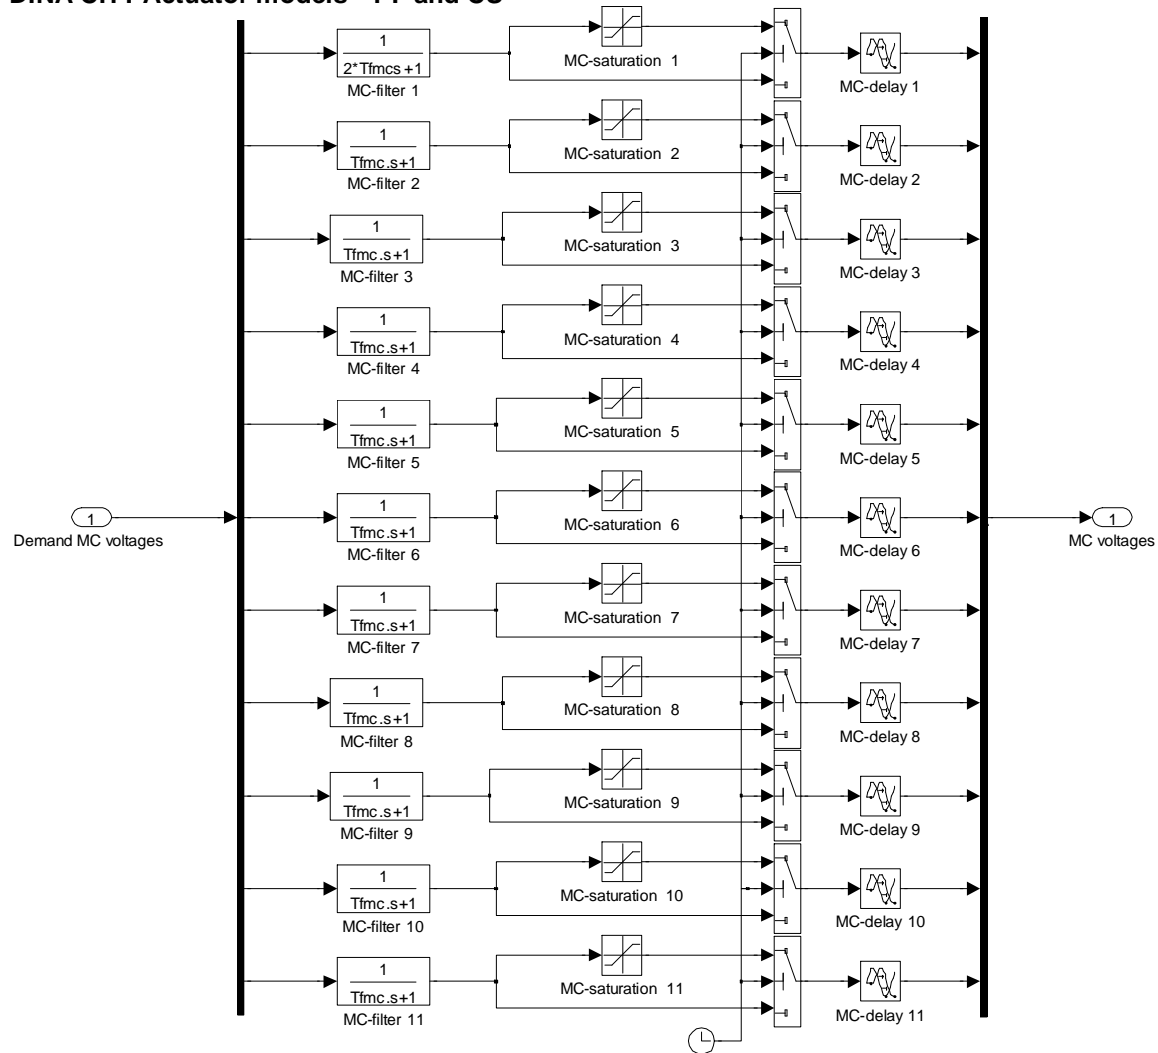

- A simulator of the diagnostic measurements

- A feedback controller to track the references already defined with weights already determined

# Simulate all the actuators

DINA-CH : Actuator models - PF and CS

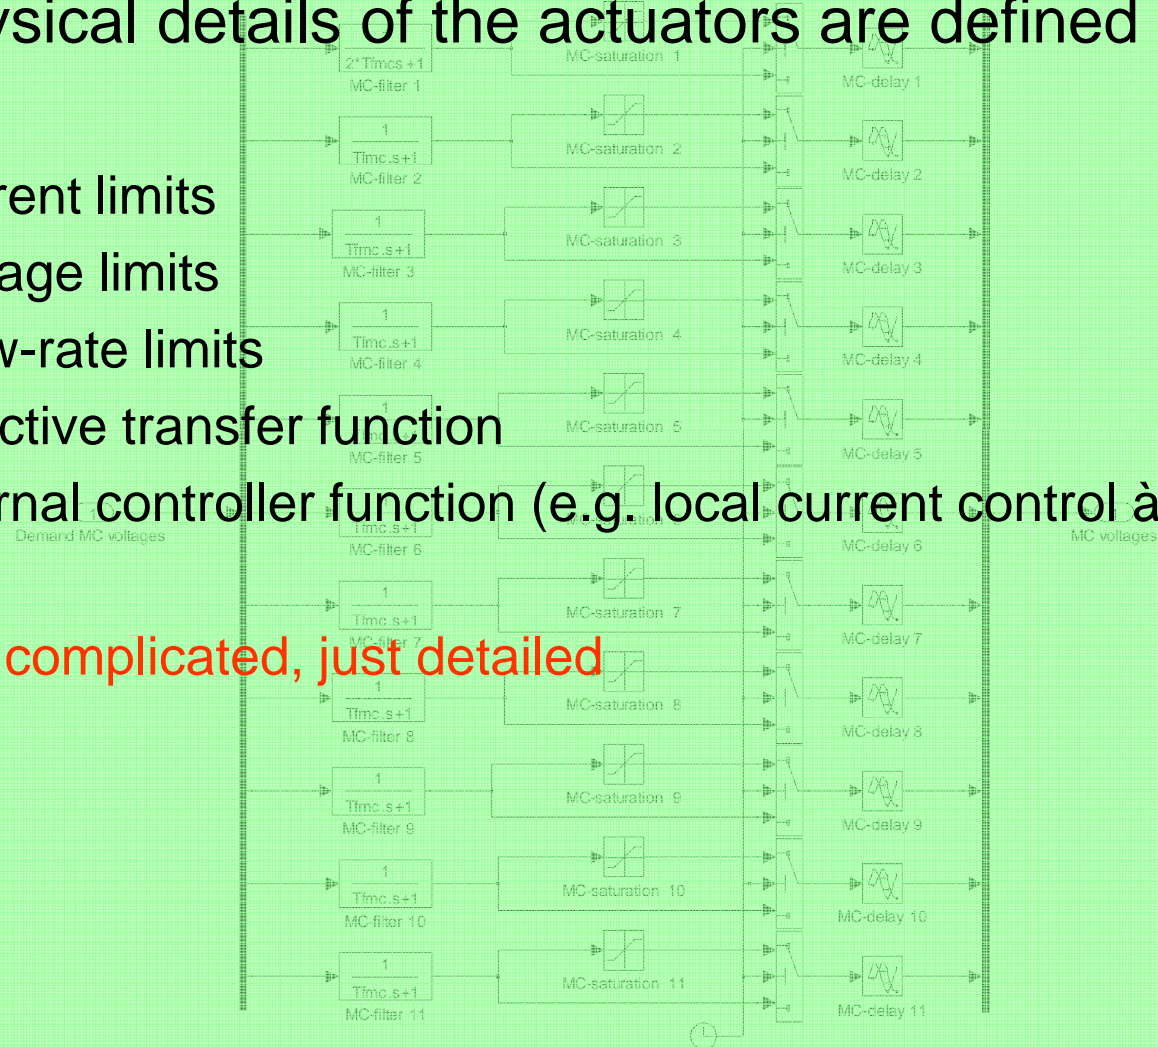

# Simulate all the actuators

## ■ All physical details of the actuators are defined

- Current limits
- Voltage limits
- Slew-rate limits
- Effective transfer function
- Internal controller function (e.g. local current control à la AUG)

This is not complicated, just detailed

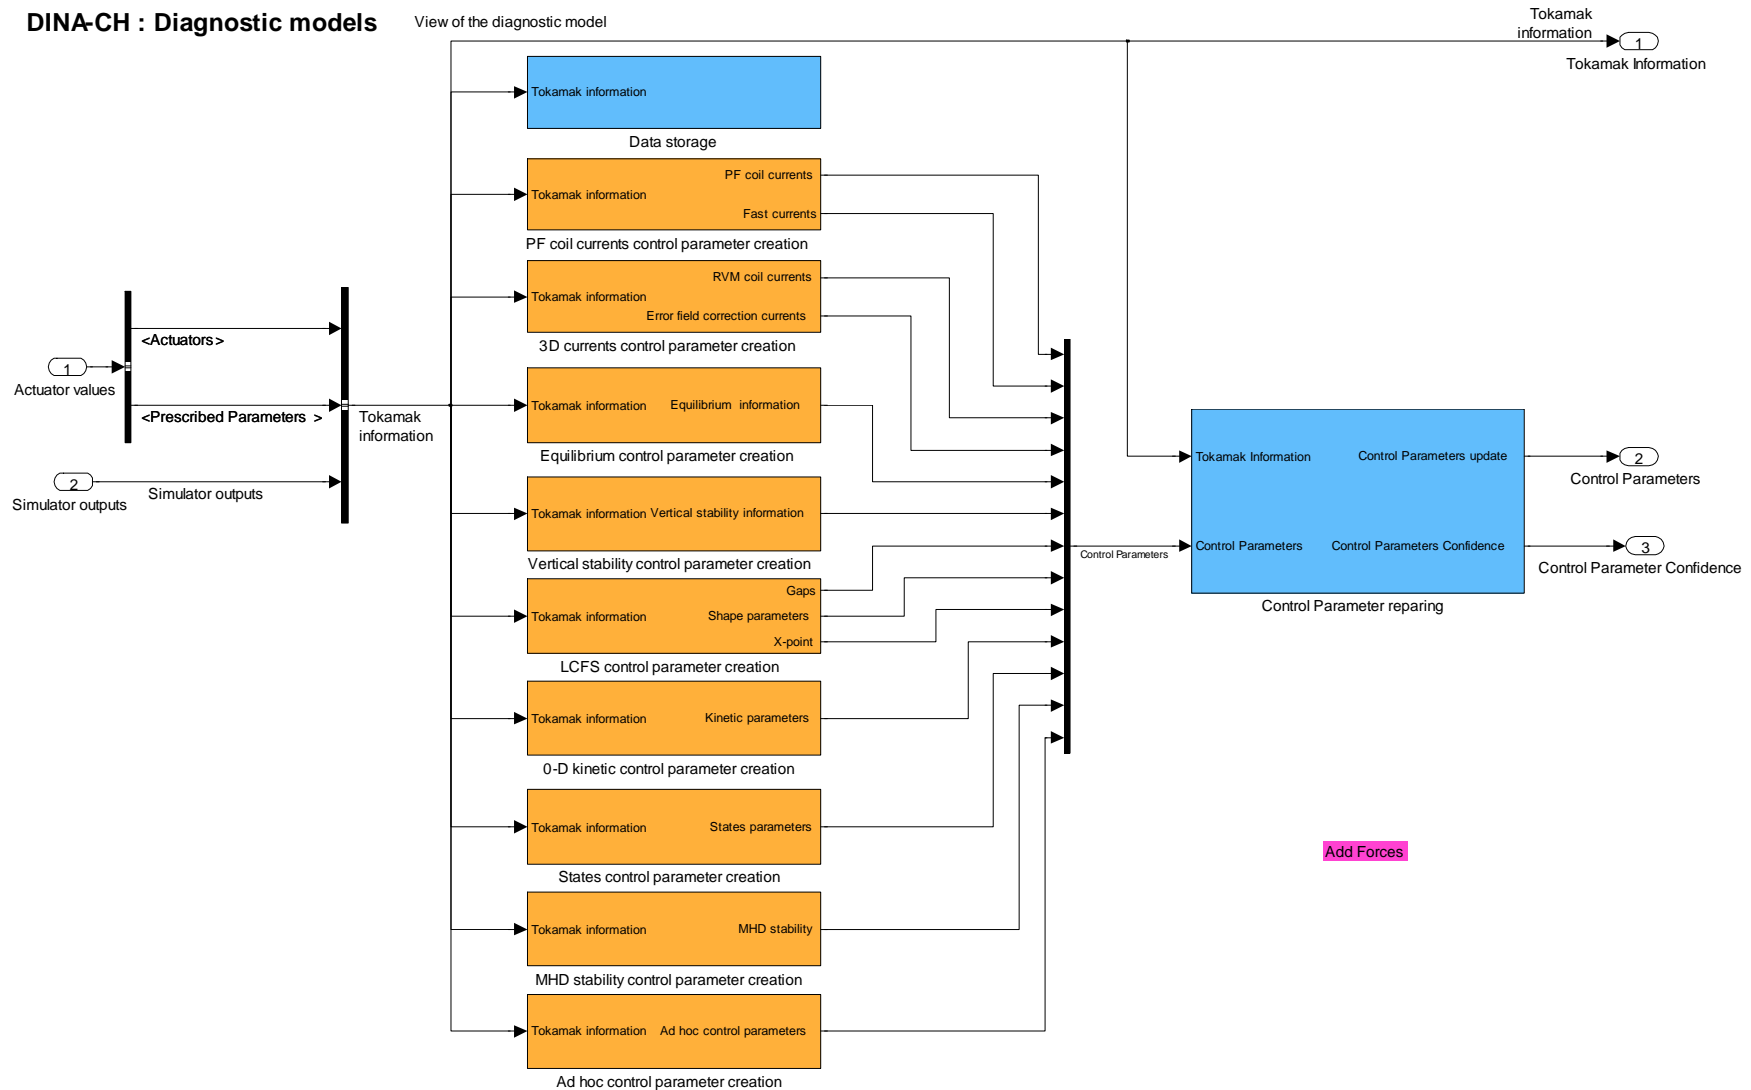

DINA-CH : Actuator models - PF and CS

# Simulate all the diagnostics

## DINA-CH : Diagnostic models

View of the diagnostic model

# Simulate all the diagnostics

DINA-CH : Diagnostic models

View of the diagnostic model

Tokamak information

Tokamak Information

- We need to output ALL inputs to ALL controllers
- All physical details of the diagnostics are defined
- We use the psitoolbox for generic diagnostics, an alternative to FLUSH
- Some diagnostics come directly from the tokamak simulator
- Some diagnostics are generated indirectly from the tokamak simulator outputs

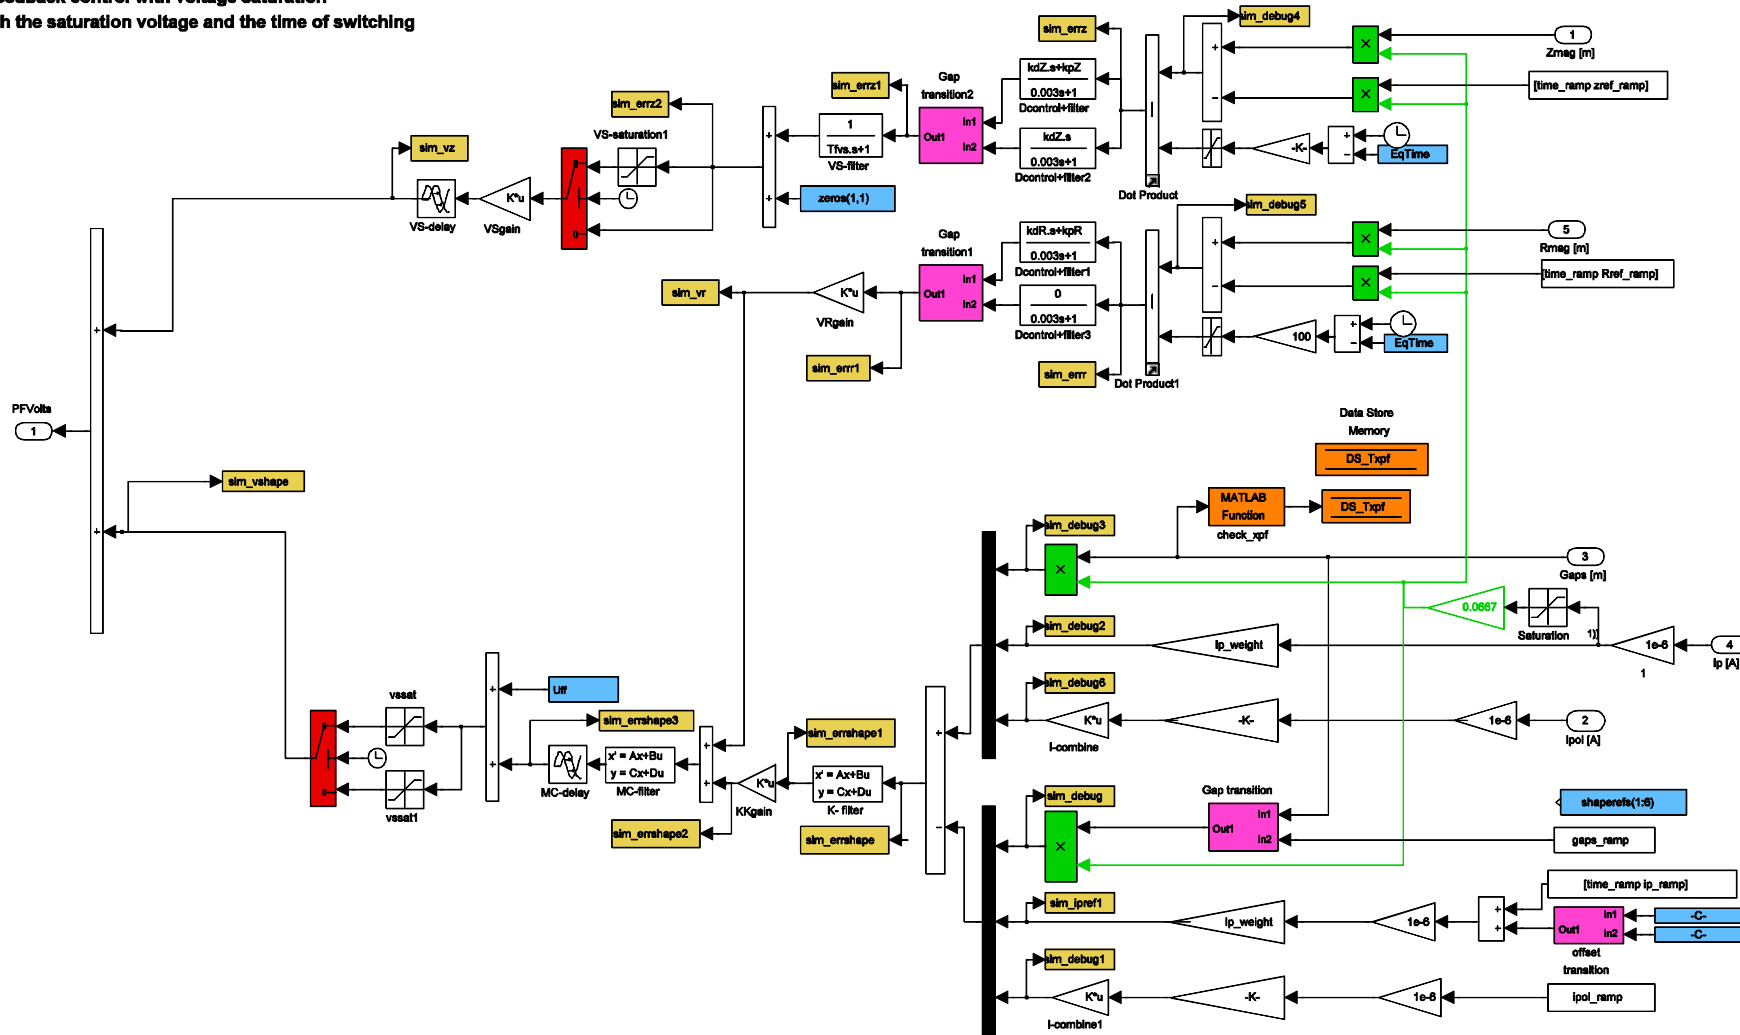

Not complicated, just detailed understanding of the equipment

Ad hoc control parameter creation

# Simulate all the controllers - 1

## Feedback control with voltage saturation

Be careful with the saturation voltage and the time of switching

# Simulate all the controllers - 1

- This initial deployment of the controllers and actuators under Simulink was simple and quick, but understanding it and maintaining it was painful and slow...

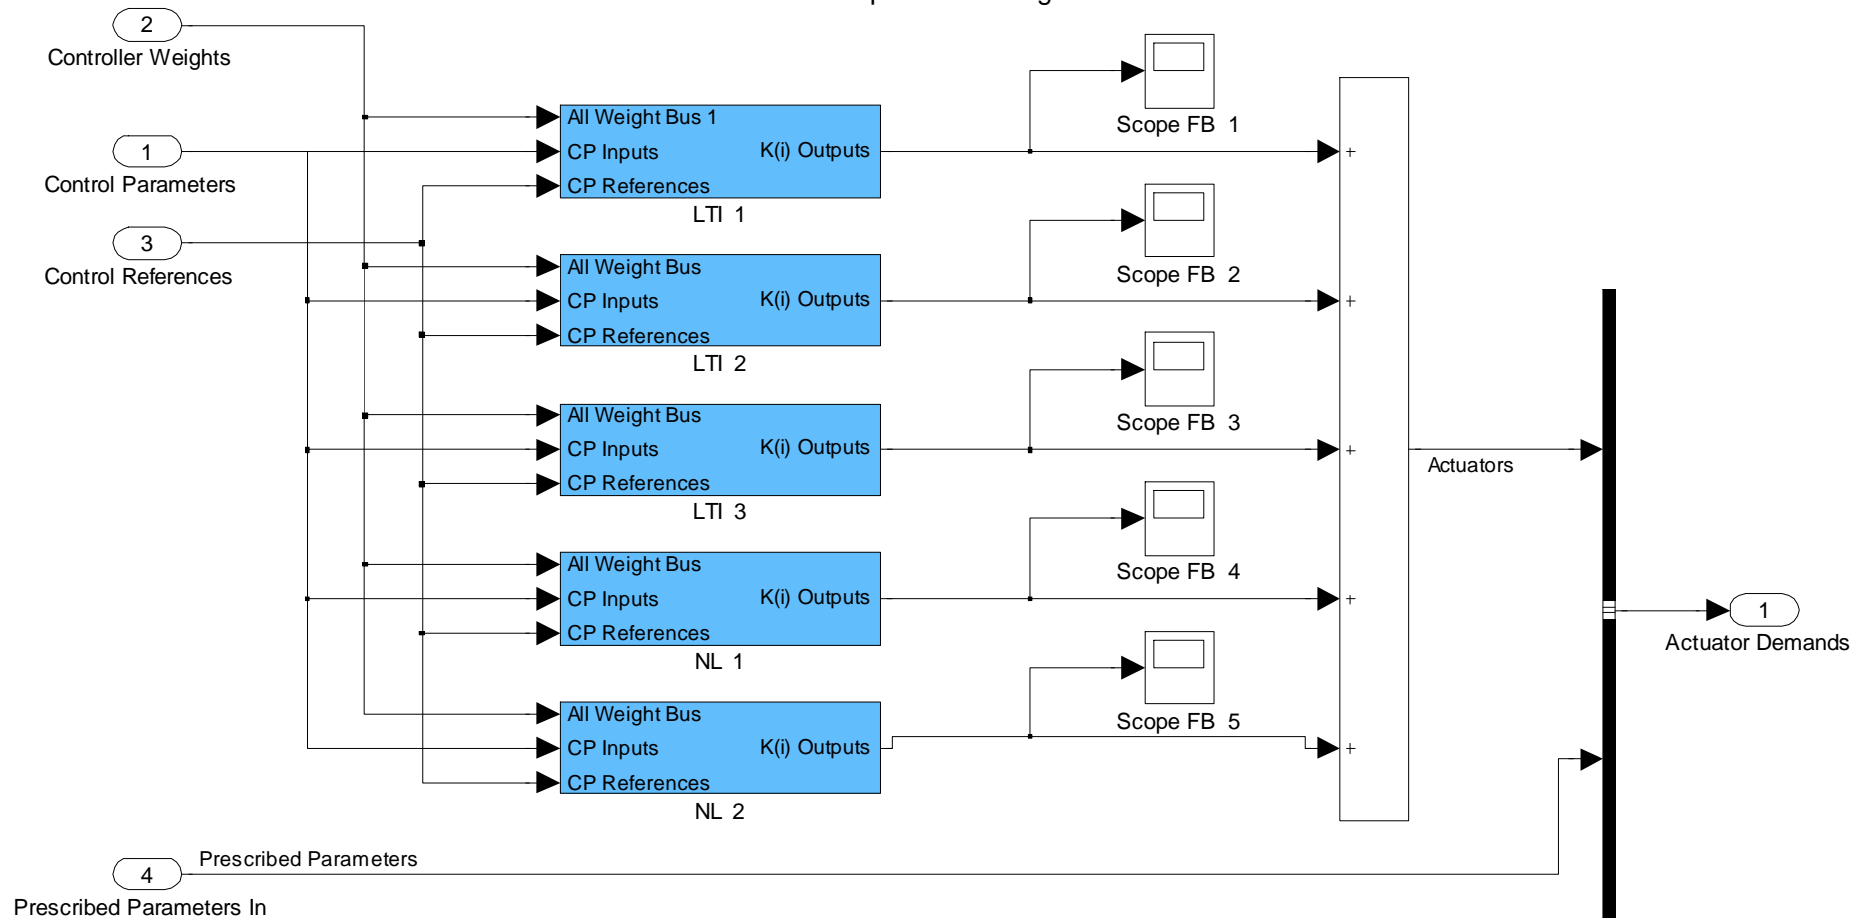

... but it worked very well

Feedback controllers, feedforward controllers, controller switching, supply slewing, saturation, delays etc all had to be included

# Simulate all the controllers - 2

## DINA-CH : Feedback Controller set

3 LTI and 2 NL Controllers are all fed with references, current status and a bus of weights  
 The weights are used for switching controllers  
 The outputs of all weighted controllers are summed

## Simulate all the controllers - 2

### ■ The re-deployment assumed:

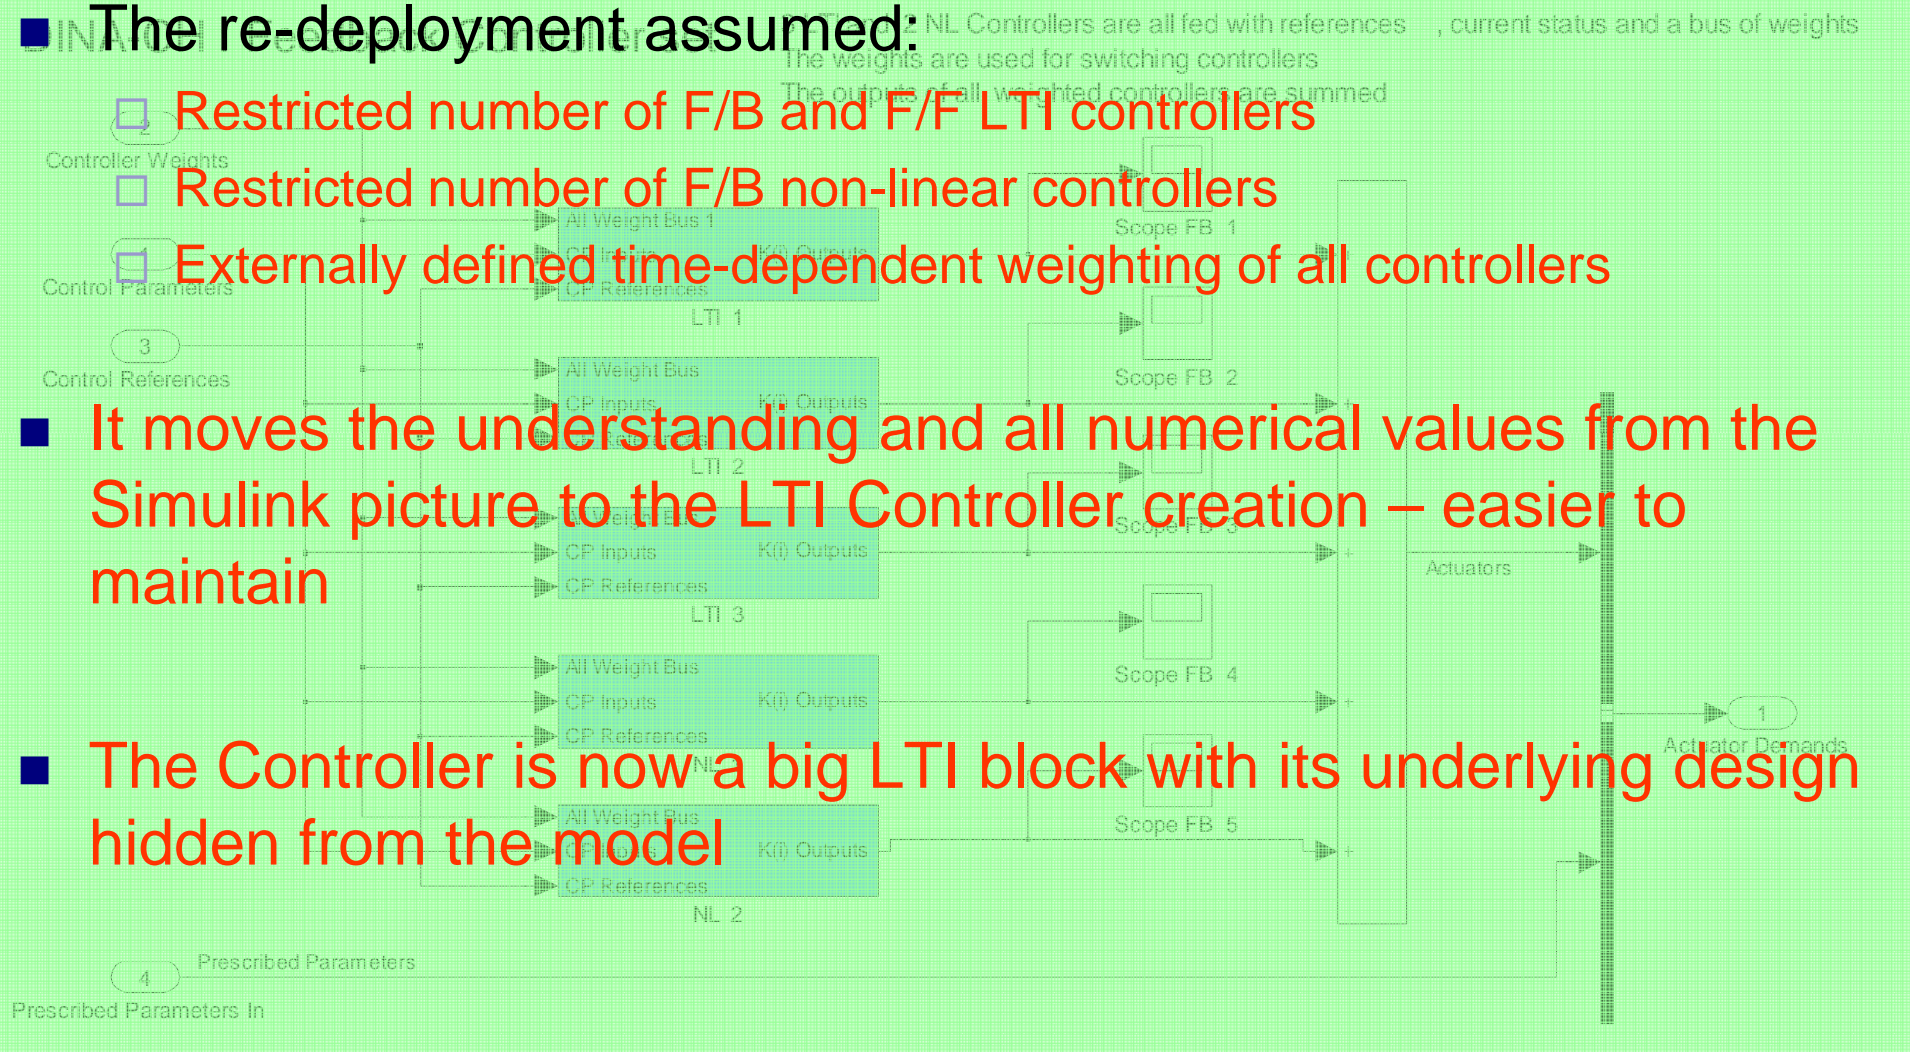

□ Restricted number of F/B and F/F LTI controllers

□ Restricted number of F/B non-linear controllers

□ Externally defined time-dependent weighting of all controllers

■ It moves the understanding and all numerical values from the Simulink picture to the LTI Controller creation – easier to maintain

■ The Controller is now a big LTI block with its underlying design hidden from the model

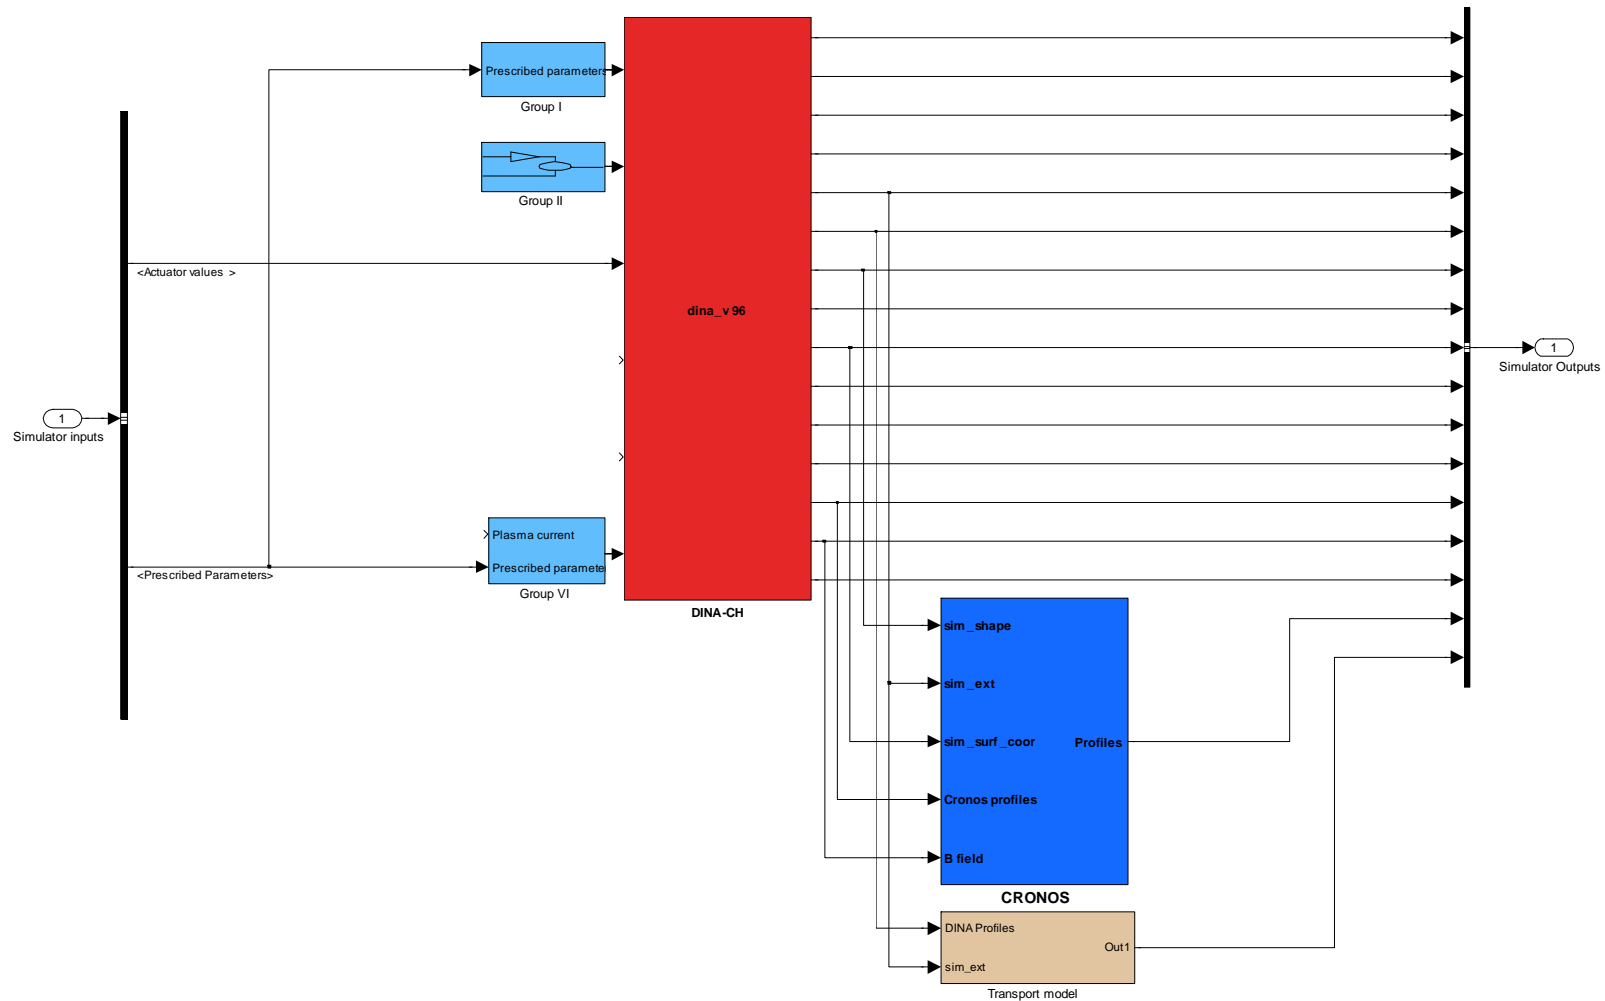

# Simulate the bare tokamak – the Tokamak Core Solvers

DINA-CH : Full tokamak evolution

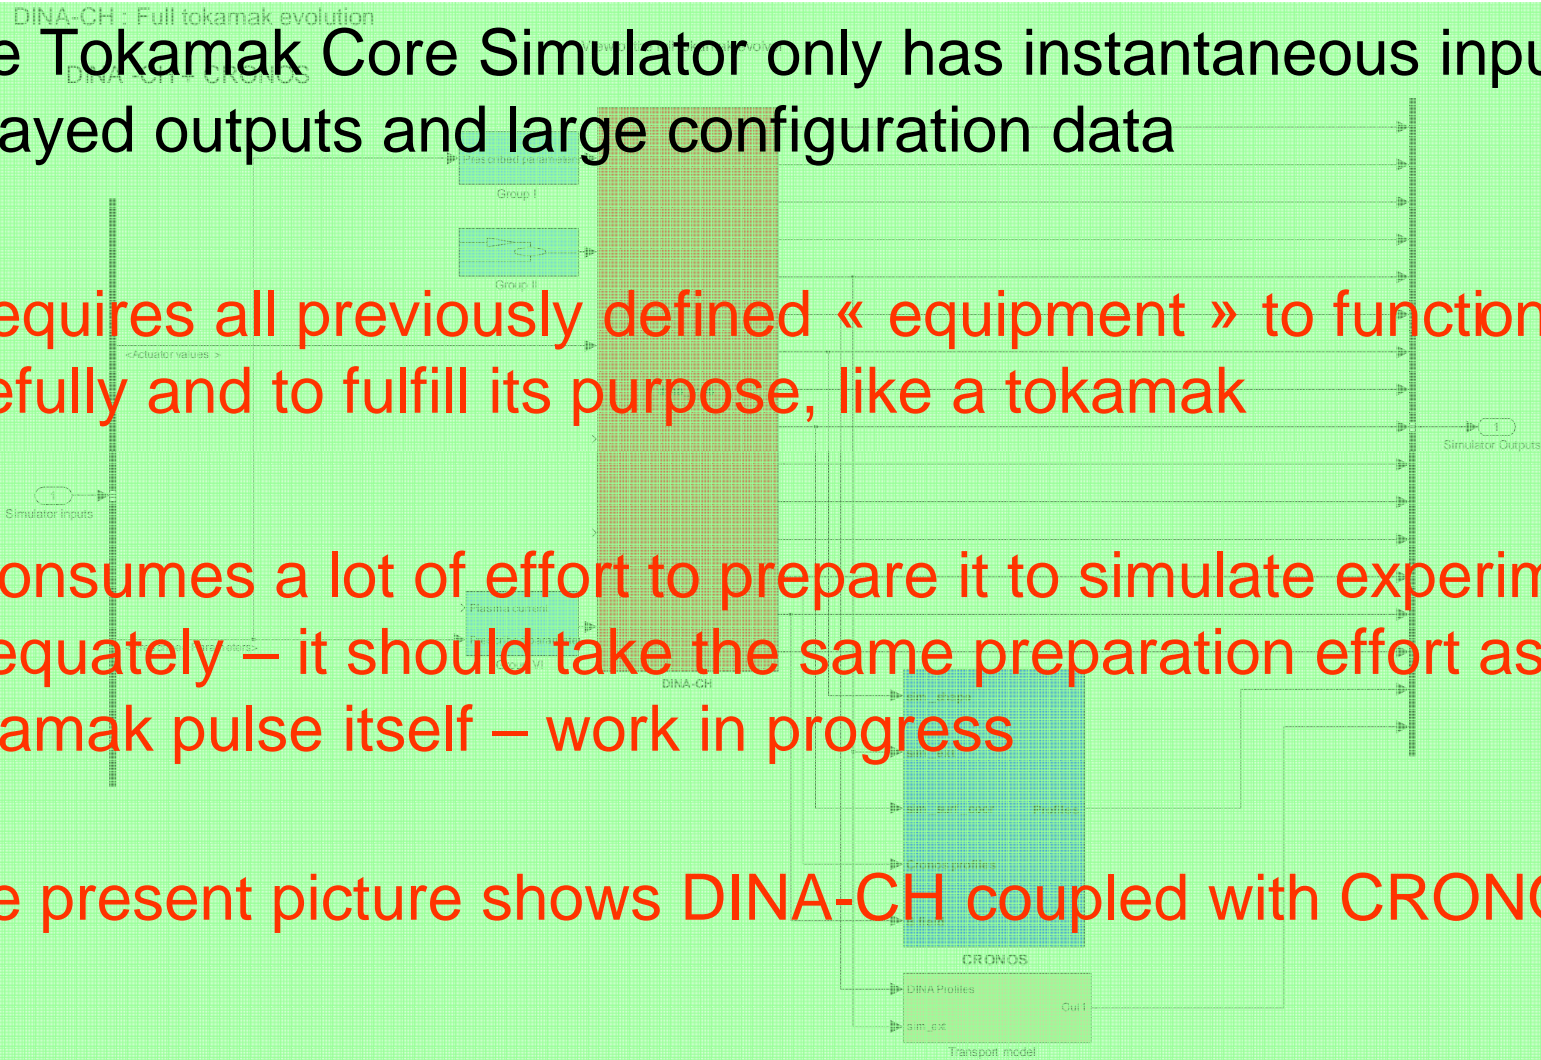

View of the full tokamak evolver

DINA -CH + CRONOS

# Simulate the bare tokamak

- The Tokamak Core Simulator only has instantaneous inputs, delayed outputs and large configuration data
- It requires all previously defined « equipment » to function usefully and to fulfill its purpose, like a tokamak
- It consumes a lot of effort to prepare it to simulate experiments adequately – it should take the same preparation effort as a tokamak pulse itself – work in progress
- The present picture shows DINA-CH coupled with CRONOS

## What is the solver solving ?

- Electromagnetic equations linking voltages and currents
- Force balance equation linking profiles to vacuum field (GS)
- Deformation and movement of the free-boundary equilibrium creating voltages
- Heat transport equations linking sources and conductivities to temperature changes
- Temperature changes influencing the transport coefficients

## So where was the problem ?

- That looked too simple, just create the bits and add the solver
- It was done in 1993, so why is it still a challenge ?

## Convergence difficulty

- Converging the EM part and the transport part separately is based on an assumption that thermal evolution is slower than EM evolution
- This is broken with, for example, ELMs and sawtooth crashes
- Convergence of the 2 branches is always a challenge
  
- Converging heat and current transport is 1-D
- Converging free-boundary induction is 2-D
- 1-D to 2-D mapping is always a challenge and time-consuming
- A pure 2-D solver is a future challenge worth meeting ??
- Does the increased complexity reduce the work to be done ?

## Convergence difficulty

- Free boundary evolution moves the target for ECH deposition and moves the LH coupling – just 2 examples
- These modules have to resist rapid changes creating unphysical noise in the deposited power
- The separatrix is mathematical, not physical, since there are no physical discontinuities
- It is difficult to assess what the future difficulties will be with a new solver, we can only illustrate some of the lessons learned

# Simulate the bare tokamak – new solver

It might be worth revisiting the PCS and Core Tokamak Solver CPOs early to understand the usage  
Do they fit today ??

# Lessons learned - Tokamak Core Simulator - 1

- A self-consistent initial startup is a bigger challenge than on the experiment – minimise startup transients
- Obtaining a reliable match between feedforward and startup should be like the experiment
- An intermediate restart is essential due to full pulse execution times – it was quite a job to continuously export enough data to make a perfect restart – this should be built in on Day #1 – not discover it later
- Time-stepping – for ITER simulations, the time-step is 2.5 to 3 msec for PF voltages. Take care that the kinetic updates are not faster

## Lessons learned - Tokamak Core Simulator - 2

- DINA-CH and CRONOS were coupled by choice because they were both already implemented under Matlab
- Careful to decide “who does what” and not to have to sort it out afterwards
- Initial coupling required 2-D equilibrium convergence by both codes, and this took forever and was abandoned as not useful
- The solution adopted was to allow
  - CRONOS to step forward the kinetic profiles using the source and transport modules, imposing them on DINA-CH
  - DINA-CH to step forward the current diffusing free-boundary equilibrium, imposing it on CRONOS

## Lessons learned - Tokamak Core Simulator - 3

- Manipulating the large data-sets generated requires the same attention as experimental data – but ITM has this view already

# Tokamak Core Simulators – are we there yet ?

- Is DINA-CH-CRONOS a perfect black-box solver ??
- Not yet...
  - Initialisation is still a black art
  - Pulse scheduling is under development with ITER
  - Crashes of the core solvers are relatively undiagnosed and therefore hard to track down and time consuming
  - Consistency check on whether the simulation input data are acceptable
  - Generally, how do we reduce the rate of “failed” simulations
  - What is a “failed” simulation
- When we are there, the different core solvers should be able to produce identical results from identical pulse schedules
- This is over the horizon today....
